1 New Code / Devs

1.1 Python Terminal Script for Filtering

Due to the fact that we to filter multiple simulations with very similar methods, I decided to make an actual script instead of just using a notebook repeatably. The largest upside is that this can easily be run on a compute node, which makes filtering larger sims easier. Also helps make sure any results are reproducible.

Takes a user input via the CLI (see below), filters for all **BH_Sol** systems, and returns the population file with said systems. Additionally, it returns a .csv of just the **BH_Sol** rows. While running it provides feedback via the terminal stating how many **BH_MS** systems it found, as well as how many are the expected **S1:S2** configuration. If any are **S2:S1**, it prints a warning as well as the total count.

Need to further refine it, but there's also a default SBATCH script to help expedite the submission process.

Usage Example

```
python BH-Sol_Filter.py /Data/1e+00_Zsun_population.h5 -o ./testResults
```

Arguments

Argument	Use	Ex value
<code>-o</code>	output location	.results
<code>-outputName</code>	name for the outputed files ¹	BH_Sol_Systems
<code>-overwrite</code>	Whether to overwrite existing results, T/F bool. Defaults to F	True
<code>--maxMass</code>	Max mass used when filtering, defaults to $3M_{\odot}$	3.5
<code>--maxPeriod</code>	Max period used when filtering, defaults to 3.5 days	4

Can be found at https://github.com/PiersonLip/stellarBHs/blob/main/FilteringScripts/BH-Sol_Filter.py

¹If a name is not specified it will use the original filename, appending a specifier to the front

2 New Research

2.1 Pop 1

When filtering via notebook and script, both returned 6 systems that had $p_{orb} < 3.5, M_{\odot,2} < 3, t < 10e9$

These systems all evolved via the same channel, ZAMS_oCE1_CC1_oRL02_CC2. Via inspection of the history df and the oneline, it is evident that the systems evolve detached, then into post-MS **unstable** RLO via $S1 \rightarrow S2$. This period decrease leads to common envelope, which then *greatly* decreases the orbital period. The envelope is then ejected, leaving a depleted stripped He core². The core then collapses in a couple of thousand years, leaving the system in a BH-MS state with low p_{orb} /seperation.

These systems then evolve in a semi-peculiar way, where it is highly likely that there will be RLO from S2 onto S1, and because $S1 > S2$, the transfer is stable, leading to *very* prolonged stable RLO (seemingly on the scale of $> 10Gyr$), which leaves S2 at low masses ($< .08M_{\odot}$).

Interestingly, the initial period for all the systems is close to $4000d$, with mean of 4022 and a std of only 151. However, a larger sample size is needed to confirm this.

Additionally, the initial masses of S1 and S2 appear to be quite constrained as well.

	orbital_period.i		S1_mass.i		S2_mass.i
count	6.000000	count	6.000000	count	6.000000
mean	4022.716197	mean	17.515761	mean	2.296788
std	151.522384	std	0.520269	std	0.320702
min	3873.118288	min	16.815111	min	1.797809
25%	3908.300983	25%	17.190036	25%	2.120753
50%	3978.305326	50%	17.510176	50%	2.353828
75%	4124.397101	75%	17.818155	75%	2.547210
max	4248.507680	max	18.254965	max	2.620529

2.2 Pop 2

Ran a second grid including an eccentricity distro (Ps and Qs), as well as slightly constraining the dataset further ($12 < M_1 < 100, .1 < M_2 < 10$)³, hoping to confirm some of the initial conditions.

	orbital_period.i		S1_mass.i		S2_mass.i
count	12.000000	count	12.000000	count	12.000000
mean	4136.066721	mean	2.240382	mean	17.357478
std	177.676729	std	0.412075	std	1.073496
min	3844.570082	min	1.551266	min	15.506937
25%	4024.214908	25%	1.903135	25%	16.714083
50%	4119.397535	50%	2.300024	50%	16.998229
75%	4273.345845	75%	2.579111	75%	18.162633
max	4370.857404	max	2.729828	max	19.435080

²I need to read a lot more about CE evo, but my intuition feels weird about the fact that just the envelope of *one* of the stars is ejected

³This is very constrained very early, but I wanted to try something while waiting for the 10 million sim

2.3 Full P_{orb}

When filtering population 2 with a max $p_{orb} = 300\text{days}$ we find 46 BH-Sol systems, all of these (except one!) evolve via the same CE channel. This suggests that there isn't a unique identity placed on BH-Sol systems with $p_{orb} \leq 3\text{days}$ ⁴, and thus it makes more sense to investigate the population as a whole. Note that there is one system which does *not* do RLO before CC1, and only reaches a solar-like mass after RLO2 (upon which it also fails), so I'm excluding it for now. Likely important to keep in mind though.

Figure 1: Masses at initial BH-Sol state. i.e. BH formation/S1 collapse

⁴This orbital period distribution is possibly due to natal kick velocities, and is suggested by the literature, but I could not find a strong link in the limited data.

Figure 2: Orbital Period of BH-Sol Systems at init onsent.

Figure 3: Crop of orbital Period of BH-Sol Systems at init onsent.

Figure 4: S1 mass initial distribution

Figure 5: S2 mass initial distribution

2.4 Strong Initial Masses Correlation

When plotting the individual masses of BH-Sol progenitors from Pop 2 there appeared to be a strong correlation between the two. We see this in figure 7.

Figure 6: Initial ZAMS masses of simulation two, with mass ratios from Moe17PsandQs. *Note that two failed systems have been excluded*

Initially, I figured this was a biasing from the mass ratio scheme in the simulation being passed through, so I ran another grid with a `secondary_mass_scheme = 'flat_mass_ratio'`. While this would also introduce biasing, I was expecting it to be largely different enough from Moe, and thus could tell if it was simply an artifact or a real correlation.

Figure 7: Initial ZAMS masses of simulation two and three. *Note that 3 failed systems have been excluded*

3 To-Do

- Find out if it makes sense for the onset of un-stable rlo to happen at $P_{orb} \approx 4000\text{days}$

4 Questions

- Tried running a grid, seems to have just completely failed from trying to reference itself before it was fully initialized. Entire log was filled with

```

```

and from what I can tell, this happened to nearly all the simmed binaries

- Should we include an initial eccentricity distribution? I imagine it would impact formation with unstable RLO and CE.
- Does it make sense to still be filtering for $p_{orb} < 3\text{days}$? The simulations seem to be suggesting that *all* BH-Sol systems evolve through CE, and that the main thing effecting p_{orb} post CE is the kick strength of the BH. So, maybe we should be initially filtering for all BH-Sol, and if we want the formation rate of specifically low p_{orb} ones, just take the subpop.
- Cool if I present an assortment of general POSYDON things I've worked on at astrofest?
